More Spanning Tree Algorithms

Instructor: Krishna Venkatasubramanian

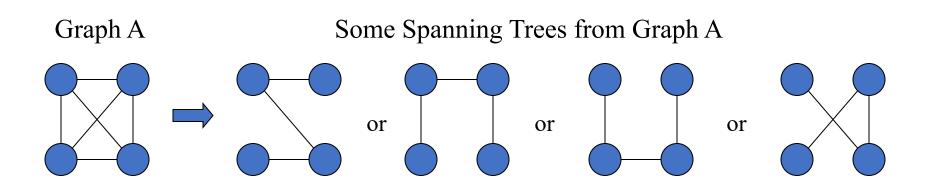

CSC 212

Announcement

- Quiz 6 (Last quiz) next Tuesday
 - Dec 10
- Assignment 3 due next Tuesday by midnight
 - Dec 10
- Academic Accommodations
 - Please email me if you need accommodations for the final exam – we can work something out
 - Please do by this tomorrow, Friday (Dec 6) 5pm
- Course Evaluation

Spanning Trees (RECAP)

- A spanning tree of a graph is just a subgraph that contains all the vertices and is a tree.
- A graph may have many spanning trees.
- Spanning trees are defined for connected undirected graphs
- Since there are trees → They have no cycles

Algorithms for Obtaining the Minimum Spanning Tree

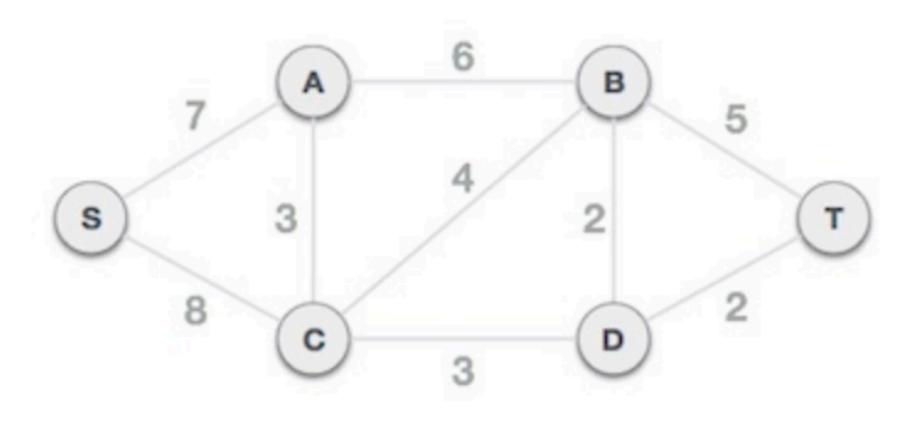

Kruskal's Algorithm

• Prim's Algorithm

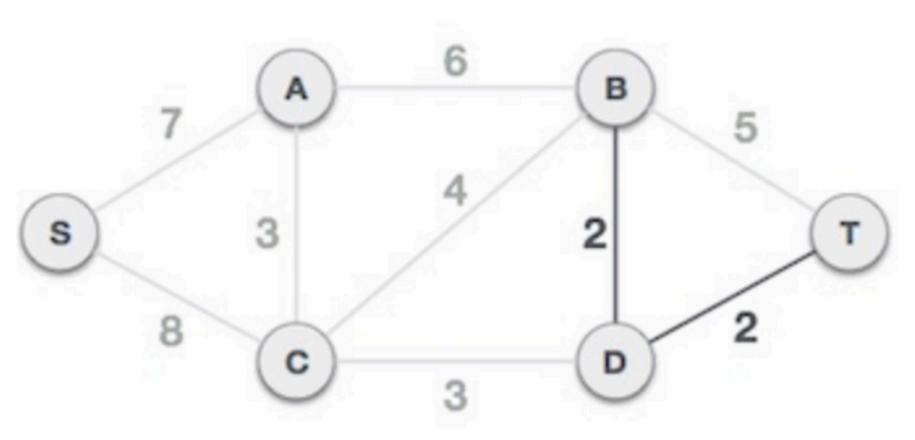

Both of these are Greedy Algorithms

Kruskal's Algorithm: Overview (RECAP)

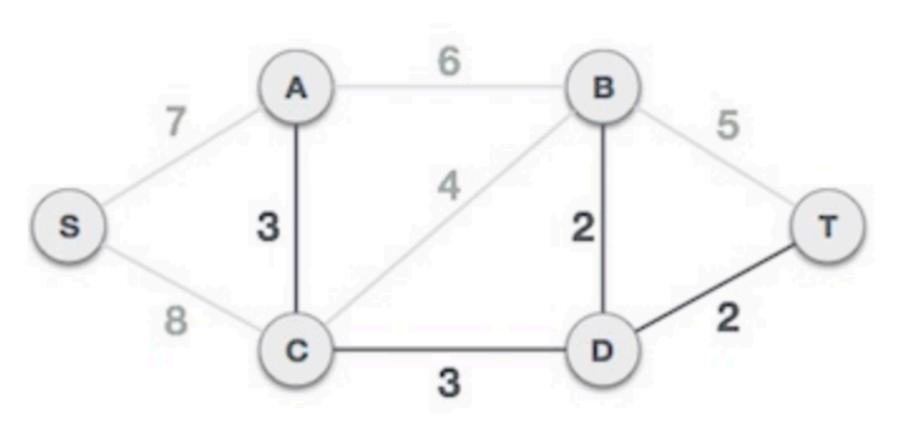

- 1. The forest is constructed with each node in a separate tree.
- 2. The edges are placed in a min-priority queue.
- 3. Until we've added n-1 edges,
 - 1. Extract the cheapest edge from the queue,
 - 2. If it forms a cycle, reject it,
 - 3. Else add it to the forest. Adding it to the forest will join two trees together.
 - If we start with n nodes (n separate trees)
 - Each step we connect two trees
 - Then we need (n-1) edges to get a single tree

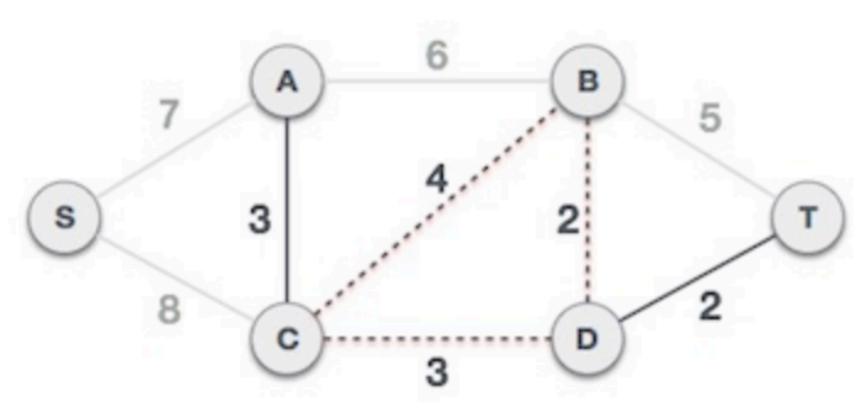

Find the minimum spanning tree for this graph using Kruksal's method

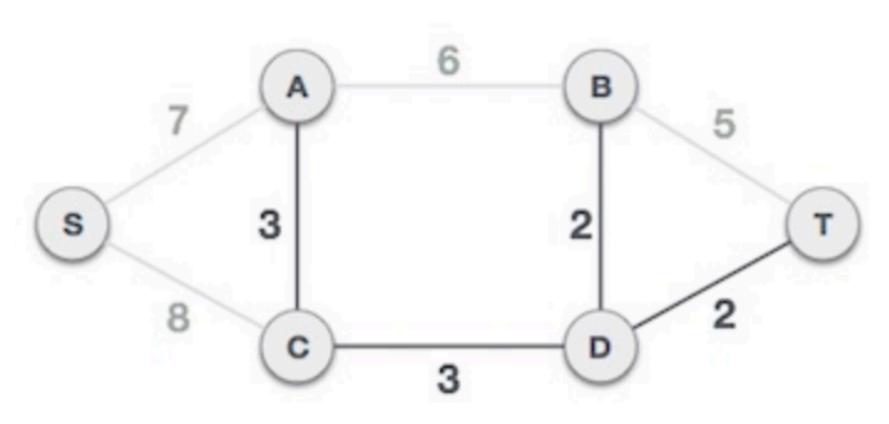

- The least cost is 2 and edges involved are B,D and D,T. We add them.
- Adding both these edges does not create loops

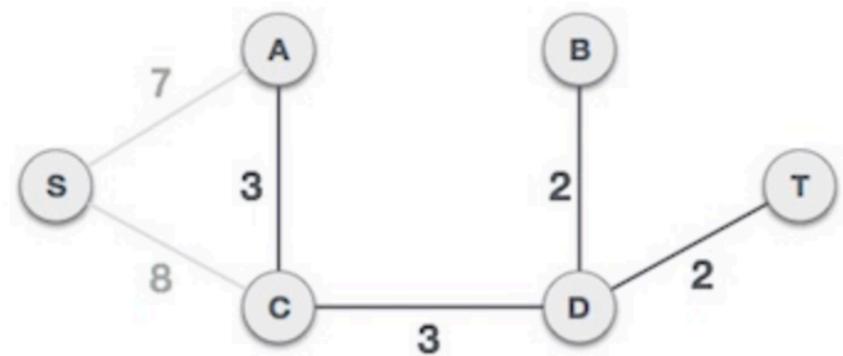

- Next cost is 3, and associated edges are A,C and C,D.
- Adding both edges to MST don't lead to loops

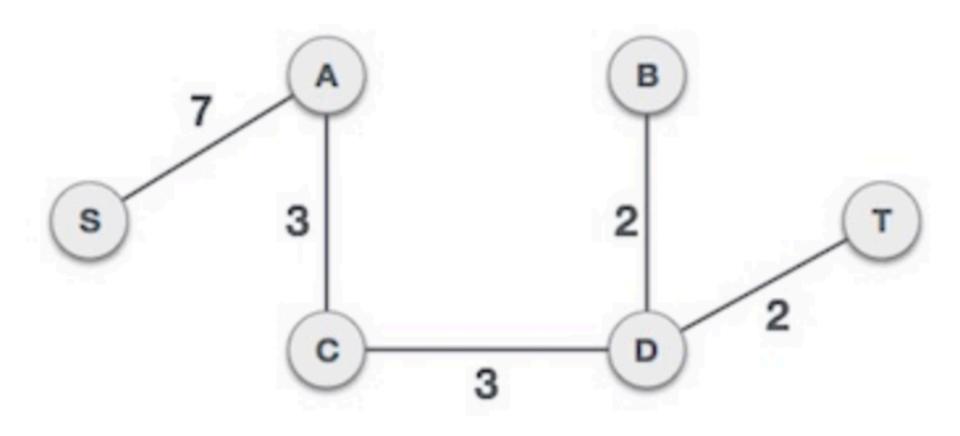

- Next cost in the table is 4, and we observe that adding it will create a loop in the MST
- Ignore edge C,B

 We observe that edges with cost 5 and 6 also create circuits. We ignore them and move on.

- Now we are left with only one node to be added.
- Between the two least cost edges available 7 and 8, we shall add the edge with cost 7.

Priority Queues (Recap)

Priority Queues

- A heap-based way for prioritizing things
 - It's called Queues, but it's implemented using a HEAP
- A queue where we add objects, each with a value ("priority").
- Priority queues are very common for job scheduling
- Two Types:
 - Max-Priority Queue we use MAX-HEAPS
 - Min-Priority Queue ← we use MIN-HEAPS

Operations on Priority Queues (Assume MIN-HEAP Priority Queue)

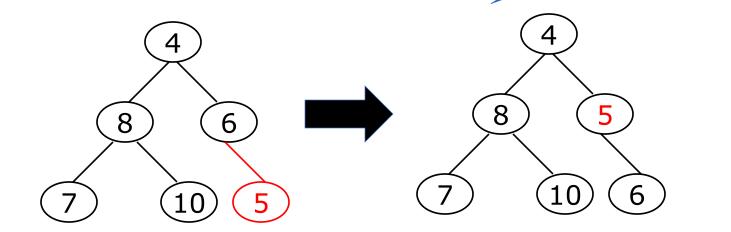

- 1 → Add a new object with priority K
- 2 > Return/Extract the object with the lowest priority
- 3 > Remove the object with the lowest priority
- 4 → Decrease the priority of object O

Heap data structure can implement all these operations efficiently

1- Add New Object With Priority 5

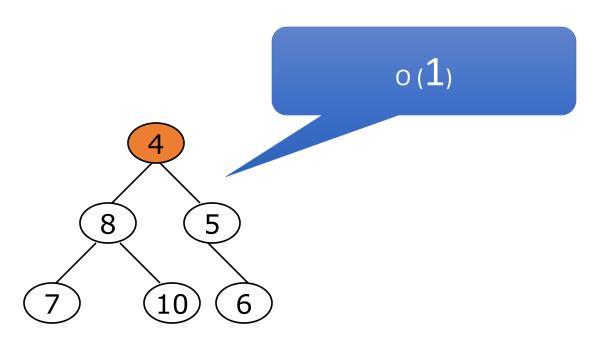

Add the object to the heap

 Check parent and move node upward iteratively O (Log n)

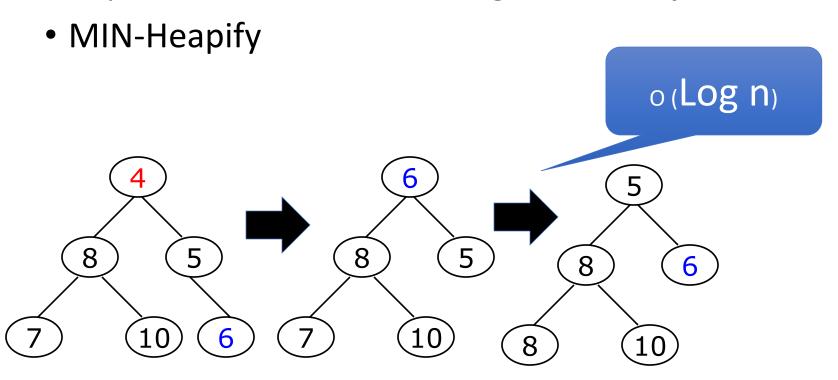

2- Return/Extract the Lowest-Priority Object

- Return the root of the tree
- Same as: Return the first element in the Heap array
- In our example, return 4

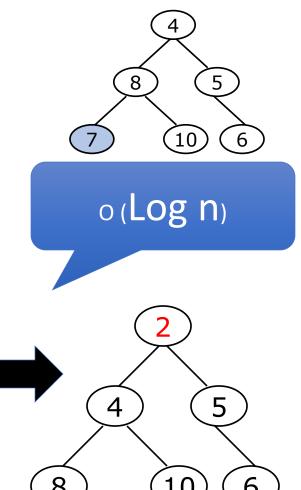

3- Remove the Lowest-Priority Object

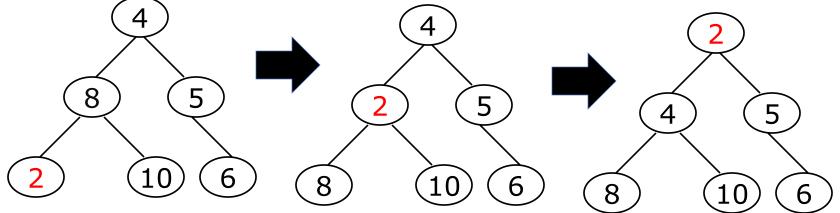

- Remove the root of the tree
- Replace it with the lowest right-most object

4- Decrease the Priority of Object

- Change 7 to 2
- Check parent and move node upward iteratively

Graph Asymptotic Growth Rates

More Asymptotic Growth Rates

- A graph G has to elements
 - V vertices
 - E edges
- Complexity of graph algorithms is usually expressed in terms of a function of V and E

 So it's good to have an intuition for the relative run-time complexity seen in graph algorithms

Order the following (in the worst case)

- O(E), O(EV), O(E²), O(V²), O(V)
 - $O(V) < [O(E) \sim O(V^2)] < O(EV) < O(E^2)$
 - Observation:
 - $E = V^2 V/2$. Therefore V < E and $O(V^2) < O(E^2)$
 - However, O(E) ~ O(V²)
 - O(EV) ~ O(V³), O(E²) ~ O(V⁴), therefore O(EV) < O(E²)
 - ~ is the symbol for equivalence here
 - O(E) < O(EV), of course.
- O(EV), O(V log V), O(E log E), O(E log V), O(E+V)
 - O(V log V) < O(E+V) < [O(E log E) ~ O(E log V)] < O(EV)
 - Observation:
 - O(E+V) ~ O(V²). Therefore, O(V log V) < O(E+V)
 - O(E+V) ~ O(E). Therefore, O(E+V) < O(E log E)
 - O(E log E) \sim O(E log V). Since E = O(V²), then O(log E) = O(2 log V) = O(log V)

Order the following (in the worst case)

- So what's the relationship between
- {O(V) < [O(E) ~ O(V²)]} and {O(V log V) < O(E+V) < [O(E log E) ~ O(E log V)]}
 - O(V) < O(V log V) < [O(E) ~ O(V²) ~ O(E+V)] < [O(E log E) ~ E (log V)]
 - Observation:
 - E ~ V². Therefore O(V log V) < O (E)
 - O(V) < O(V log V) just like O(n) < O(n log n)
 - O(E+V) ~ O(E) and O(E+V) ~ O(V²)

Overall Ordering (in the worst case)

$$[O(log E) \sim O(log V)] < O(V) < O(V log V) < [O(E) \sim O(V^2) \sim O(E+V)] < [O(E) log E) \sim O(E log V)] < O(EV) < O(E^2)$$

O(E log E) and O(E log V) are equivalent as O(log E) and O(log V) are equivalent O(E), O(V^2), and O(E+V) are equivalent

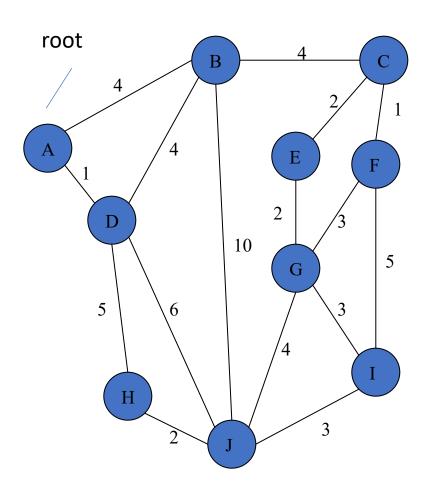

Back to MST: Prim's Algorithm

Prim's Algorithm

- 1) Assign a key value to all vertices in the input graph. Initialize all **key values as INFINITE**.
- 2) Assign key value as 0 for the first vertex so that it is picked first and call it ROOT
 - a) The parent of the root is NIL
- 3) Add all nodes into a MIN-HEAP Priority Queue \rightarrow Q (slide 16)
- 4) While Q not empty

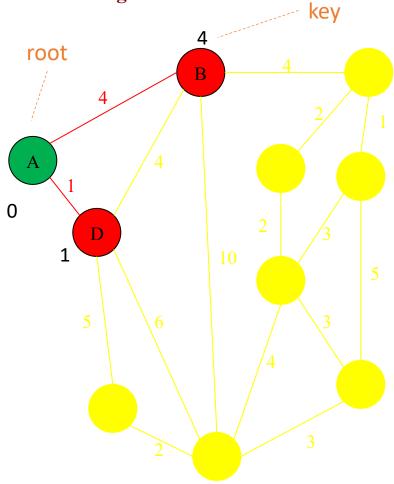

The greedy choice

-a) Pick a vertex u that has minimum key value (slide 18)
-**b)** Include *u* to mstSet (set that lists MST).
-c) Update key value of all adjacent vertices (v) of u (which is not it's parent).
 - For every adjacent vertex v, if weight of edge u-v is <u>less</u> than the previous key value of v, update the key value as weight of edge u-v
 - Make u the parent of v
 - Update the priority Q (slide 20)(i.e., min heap as we have new weights)
- ... d) Remove u from Q

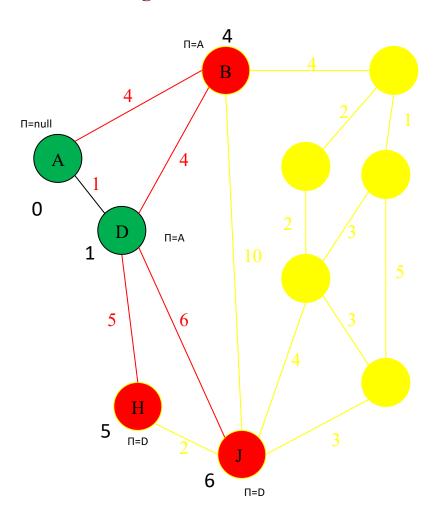

mstSet = {NULL}

- -Think of the yellow nodes as $cost \infty$ (not valid)
- -Only the red ones are being considered

 $mstSet = \{A\}$

- -Think of the yellow nodes as $cost \infty$ (not valid)
- -Only the red ones are being considered

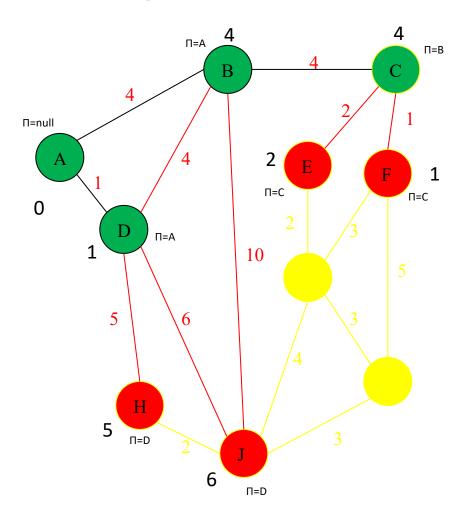

$$mstSet = \{A,D\}$$

- -Think of the yellow nodes as $cost \infty$ (not valid)
- -Only the red ones are being considered

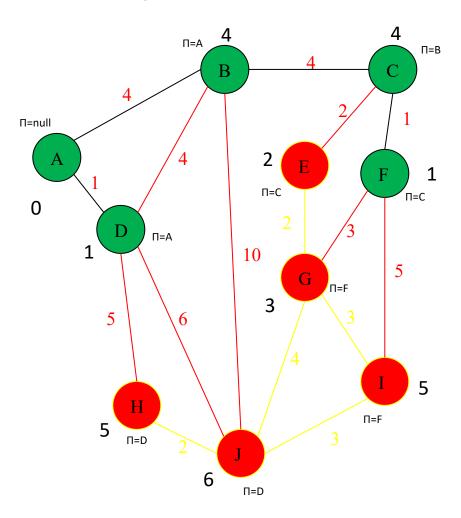

$$mstSet = \{A, D, B\}$$

- -Think of the yellow nodes as $cost \infty$ (not valid)
- -Only the red ones are being considered

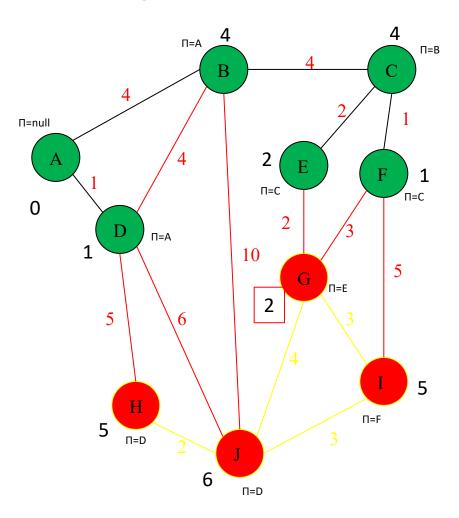

$$mstSet = \{A, D, B, C\}$$

- -Think of the yellow nodes as $cost \infty$ (not valid)
- -Only the red ones are being considered

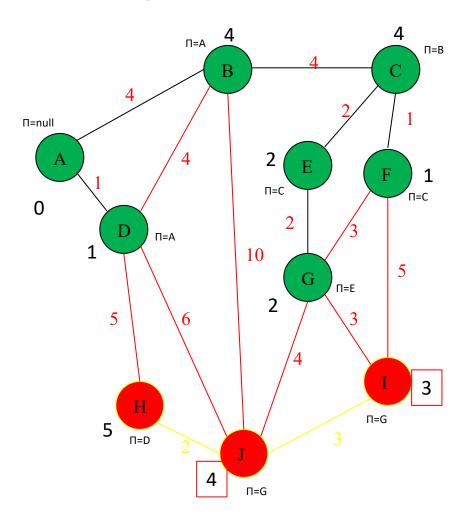

$$mstSet = \{A, D, B, C, F\}$$

- -Think of the yellow nodes as $cost \infty$ (not valid)
- -Only the red ones are being considered

 $mstSet = \{A, D, B, C, F, E\}$

- -Think of the yellow nodes as $cost \infty$ (not valid)
- -Only the red ones are being considered

 $mstSet = \{A, D, B, C, F, E, G\}$

- -Think of the yellow nodes as $cost \infty$ (not valid)
- -Only the red ones are being considered

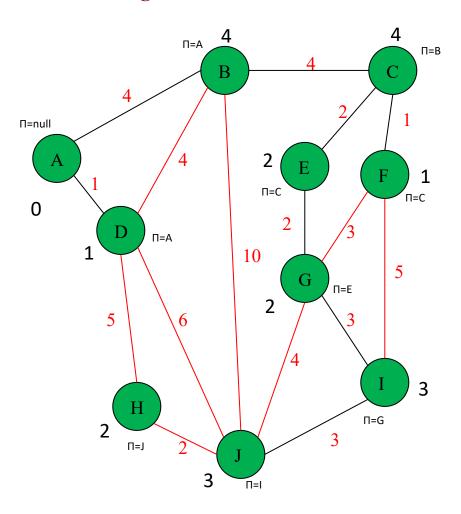

$$mstSet = \{A, D, B, C, F, E, G, I\}$$

- -Think of the yellow nodes as $cost \infty$ (not valid)
- -Only the red ones are being considered

 $mstSet = \{A, D, B, C, F, E, G, I, J\}$

- -Think of the yellow nodes as $cost \infty$ (not valid)
- -Only the red ones are being considered

$$mstSet = \{A, D, B, C, F, E, G, I, J, H\}$$

- -Think of the yellow nodes as $cost \infty$ (not valid)
- -Only the red ones are being considered

Shows the <u>order in which</u> <u>vertices added</u> to the MST

Of course this set should have all the vertices in the

graph

 $mstSet = \{A, D, B, C, F, E, G, I, J, H\}$

Total cost = 22

Krusksal's and Prim's need not produce the same MST but cost will be the same

Prim's Algorithm

1: O(V)

- Assign a key value to all vertices in the input graph. Initialize all key values as
 INFINITE.

 2: O(1)
- 2) Assign key value as 0 for the first vertex so that it is picked first and call it ROOT
 - a) The **parent** of the root is NIL

3) Add all nodes into a MIN-HEAP Priority Queue \rightarrow Q (slide 16)

3: O(V log V)

4) While Q not empty

....a) Pick a vertex u that has minimum key value (slide 18) <

....**b)** Include *u* to mstSet (set that lists MST).

4a: O(log V).

-c) Update key value of all adjacent vertices (v) of u (which is not | 4(a) is called called V
 - For every adjacent vertex v, if weight of edge u-v is less
 key value of v, update the key value as weight of edge

times in the loop.

Total cost = O(V log V)

Make u the parent of v

- 4b: O(1). Update the priority Q (slide 20)(i.e., min heap as we have new weights)
 - ... d) Remove u from Q

4(c): Has to update for each edge in the graph.

Total cost = O(E log V)

The loop repeats V times

Prim's Algorithm

1: O(V)

3: O(**V log V**)

- Assign a key value to all vertices in the input graph. Initialize all key values as
 INFINITE.

 2: O(1)
- 2) Assign key value as 0 for the first vertex so that it is picked first and call it ROOT
 - a) The **parent** of the root is NIL
- 3) Add all nodes into a MIN-HEAP Priority Queue → Q (slide 16)
- Total: $O(V) + O(1) + O(V \log V) + O(V \log V)$ + $O(1) + O(E \log V) \rightarrow O(E \log V)$
-c) Update key value of all adjacent vertices (v) of u (which is not | 4(a) is called called V
 - For every adjacent vertex v, if weight of edge u-v is **les** key value of v, update the key value as weight of edge

4(a) is called called V times in the loop. Total cost = O(V log V)

- Make u the parent of v
- 4b: O(1). Update the priority Q (slide 20)(i.e., min heap as we have new weights)
 - ... d) Remove u from Q

4(c): O (log V)

4(c): Has to update for each edge in the graph. Total cost = O(E log V)

Algorithms for Obtaining the Minimum Spanning Tree

Both of these are Greedy Algorithms
